

What is typically connected to the grounding busbar in a relay protection cabinet

Overview

Secondary System Grounding in Substations: IEC & GB/T Guide
The grounding busbar shall be connected to the main equipotential grounding network in the prote.

Key Takeaways

In a relay protection cabinet, the grounding busbar typically connects all secondary equipment, panel-mounted devices, and protective conductors to ensure a low-impedance path to earth.
Typical Connections

Secondary Equipment and Devices: All relay protection devices, control modules, and monitoring equipment mounted on the panel are connected to the grounding busbar using multi-strand copper wires, usually with a cross-sectional area of at least 4 mm², to maintain equipotential bonding and prevent maloperation during faults or overvoltages (GB/T 50976-2014) .

Panel Frame and Enclosure: The busbar is often bolted directly to the metal frame of the cabinet, providing a common reference point and ensuring that the enclosure itself is grounded .

Equipment Grounding Conductors: Conductors from individual devices, such as meters, switches, and auxiliary equipment, are bonded to the busbar to safely channel fault currents to earth, minimizing the risk of electric shock or equipment damage .

Connection to Main Grounding Network: The grounding busbar is connected to the main equipotential grounding network of the substation or protection room via a dedicated copper cable, typically with a cross-sectional area of 50 mm² or more, forming a reliable path to the station's main grounding grid .

Optional Connections: In some installations, isolated or telecommunications grounding busbars may also be connected to the main busbar to reduce electrical noise and ensure signal integrity for sensitive electronic equipment .

Purpose of These Connections

The grounding busbar serves as a central low-impedance point for all grounding conductors, ensuring that any fault currents, overvoltages, or lightning-induced surges are safely directed to earth. This prevents voltage imbalances, protects sensitive relay equipment, and maintains the stability and safety of the secondary system . By connecting all secondary devices, the panel frame, and the main grounding network, the busbar establishes an equipotential network that is critical for reliable operation of relay protection systems in substations .
